1. Introduction

Fibrodysplasia ossificans progressiva (FOP, OMIM#135100) is a rare, intractable and devastating genetic connective tissue disorder characterized by progressive ectopic ossification in the soft tissues and skeleton. Three patients, one teenage girl (P1), one male adult (P2) and one male child (P3), were studied and treated with FOPCON (combined formulation of 14 mg of propranolol and 250 mg of ascorbic acid), given three times per day. P1 started treatment in March 2012, P2 in October 2012 and P3 in July 2015. The clinical follow-up of these three patients, before initiating treatment with FOPCON, showed that FOP flare-ups used to occur frequently and that under FOPCON therapy, none of these patients had flare-ups. The striking feature of this treatment with FOPCON, is that, all three cases suffered accidental falls with documented injuries until complete healing and that where major flare-ups should occur, injuries or sequels, there was none. The present clinical observation shows that ascorbic acid plus the nonspecific beta blocker propranolol can be effectively useful, when administered previously and continually, in the prophylaxis of FOP flare-ups, especially for accidental falls. In this regard, FOPCON could be a prophylactic aid in cases of surgery of patients with FOP, hoping that it may benefit patients from having the severe sequel, characteristic of heterotopic bone formation. All three patients reported, to date, they no longer had flare-ups nor heterotopic ossification and showed normal scar healing.

Until today no treatment has been effectively able to control FOP disease. Progress has been achieved in inhibiting ossification, with Palovarotene, a retinoic acid receptor gamma agonist with low potential for side effects (4,5). In the literature there are few other drugs (6-10). Ascorbic acid treatment case reports of FOP were previously described by Palhares et al. (1997, 2001 and 2010), showing improvement of symptoms (8), decrease of flare-ups (9) and transient stabilization of crisis (10).

Because FOP disease is prone to flare-ups (II), due to any manipulations, be they accidental trauma, surgeries, dental procedures, intramuscular injections, bacterial or viral infections and stress, it becomes impossible to control flare-ups and heterotopic ossification.

In this regard, as a novelty we report three cases of FOP patients, who had accidental falls, and were benefited by a combination therapy of ascorbic acid and propranolol (FOPCON), without flare-ups or sequels.

2. Materials and Methods

The present study is a comparison of three FOP patients, one teenage girl (P1), one male adult (P2) and one male child (P3). They were clinically evaluated and followed up by medical professionals, including a pediatrician, a medical geneticist, odontologists and academic researchers at the University Hospital of The Federal University of Mato Grosso do Sul and Federal University of Minas Gerais. Patients were studied and treated with FOPCON 14.250 (Fibrodysplasia ossificans progressiva combined formulation of 14 mg of propranolol and 250 mg of ascorbic acid), given three times per day. P1 started treatment in March 2012, P2 in October 2012 and P3 in July 2015 and are part of a project approved by the University Hospital Ethics Committee (CAAE: 60117916.0.0000.0021), upon Free and Informed Consent Form, signed by patients and their caregivers (12).

P1 was born April 2002, with diagnosis within 34 months old. Her manifestation of FOP was first described by Palhares (2010) (8). P2, born April 1984, showed clinical manifestations at 30 months of age, reported somewhere else (9,10). This patient achieved adulthood and received several conventional treatments with anti-inflammatories and corticosteroids during crisis and received significant therapy. Although, otherwise healthy, the patient evolved with some control of the disease including ossification and significant loss of mobility as an adult FOP patient. On October 2012, the patient was admitted onto FOPCON therapy only. P3 was born September 2009, with bilateral hallux valgus and his first acute FOP crisis occurred when he was 7 months old.

Before FOPCON, P1 and P2 were pretreated with ascorbic acid (AA), and obtained transient stabilization of crises, subsequently propranolol was introduced combined with AA. Both cases were previously described by Palhares (8-10), featuring previous classical treatment medicines compared with the present FOPCON treatment results.

On the other hand, P3 was treated directly with FOPCON formulation. Thus, the results obtained in P3 were compared to their previous history (recorded in clinical practice) of frequent falls or traumas and consequent limitation of movement, despite the use of conventional treatments.

3. Results and Discussion

To our knowledge, the present report is the first demonstrating three cases of FOP patients, who had accidental falls with injuries, and were safe using a novel combination therapy (FOPCON) of AA and propranolol (PP), and showing, so far, no flare-ups or sequels from those injuries (Table 1).

P1 suffered a fall when running in the schoolyard leading to bruising, and a cut in the upper left eyebrow area, in June 2014, about two years after starting treatment. The skin was cleaned, repaired, and sutured with seven stitches. During the recovery phase after suture, there was no flare-up (Figure 1), and tissue showed normal resolution and scar healing. P1 has been maintained on FOPCON since that time and has shown good drug tolerance, normal blood pressure and no side effects. However, in 2017, P1 began taking FOPCON on an irregular schedule, and inadvertently, at the same time, the teen had a tattoo on her right arm drawn in December 2017, which consequently led to a large flare-up on each upper limb, compromising the hand on the same side of the tattoo. After re-introduction of FOPCON, the flare-up regressed, and she is doing active physiotherapy to improve the movements of the fingers, which were initially totally frozen. Currently, P1 is taking medication correctly and is clinically stabilized without any flare-up.

P2, previously treated with AA plus bisphosphonates, was added to a new treatment with FOPCON in October 2012. Since then, P2 has had no flare-up. Though P2 has vague complaints associated to pre-existing numerous ectopic ossifications, his overall status has improved significantly. Patient's blood pressure has always remained within normal limits, ranging 100/60 mmHg. By February 2015, during domestic transportation, P2 fell from a stretcher and suffered an injury in the soft tissue of his left leg, with good healing and did not present flare-up (Figure 2). Since he started treatment with FOPCON, he has never had any FOP crisis, showing clinical improvement, better neck movement, better sleep, and excellent mouth opening, which gradually improved, since initially it was only 30%. Now it's six years and four months of treatment with improvements, although he began his treatment under a bedridden condition.

P3 started FOPCON treatment in July 2015. P3 showed good tolerability to FOPCON without any

In the upper limbs' abduction. Typically, physical injuries or trauma in patients with severe FOP such as P3, would cause acute crisis with appearance of inflammation and swelling. However, P3 so far, shows no sign of FOP crisis. His healing evolved naturally without ectopic bone formation (Figure 3A, 3B and 3C). Later, P3 had another fall, resulting in a left humerus fracture, nevertheless, showed good recovery (Figure 3D). Recently, P3 had a left knee trauma and he had a joint effusion and pain but without FOP crisis, however parents were advised to seek orthopedic treatment.

No effective medical therapy is known for FOP, bisphosphonates and corticosteroids are only beneficial during flare-up, but do not prevent formation of ectopic bone (6). Distinct case reports reveal reasonable disease control with etidronate, including ectopic bone reduction, however, they agree that long-term use leads to osteopenia, contraindicating its continuous use in the upper limbs' abduction. Typically, physical injuries or trauma in patients with severe FOP such as P3, would cause acute crisis with appearance of inflammation and swelling. However, P3 so far, shows no sign of FOP crisis. *Dosage: FOPCON 14.250 = 14 mg of propranolol and 250 mg ascorbic acid; **irregular schedule FOPCON.
(13,14). Other groups have proposed drugs already in a clinical trial phase, however, their efficacy and side effects can be questioned (15,16). The use of AA only (11) as well as AA plus intravenous bisphosphonates (10), despite some improvement in the patients, did not avoid disease progression. Therefore, although many treatments have been reported, the disease may have shown slight improvement, but disease progression has been observed, as well as recurrence of flare-ups.

FOP crisis always appears spontaneously or due to local trauma that leads to severe inflammatory responses of connective tissue and intramuscular edema in such ways that biopsies of FOP patient’s tissues, with inflammatory processes, have shown formation of endochondral osteogenesis in heterotopic sites, causing ectopic ossification (11). Consequently, attempts to remove heterotopic ossification surgically have been mostly unsuccessful, since surgical trauma itself can provoke disease flare-ups. With the intent to block formation of new tissue, anti-angiogenic drugs such as thalidomide and Squalamine, have been used in FOP (17) for inhibition of new blood vessel formation, but failed to resolve the manifestation of FOP signs and symptoms.

The major rationale for the usage of beta-blockers comes with reports that heterotopic bone is formed along with new neurons and that enervation is important in the onset of bone morphogenesis in FOP (18). Furthermore, endochondral bone formation requires angiogenesis, so the use of propranolol may be a limiting factor in this process, because without angiogenesis, there would be no vessels to form bones (19) and beta-blockers are anti-angiogenic, while propranolol usage has shown effectiveness in the treatment of hemangiomas (20,21). How FOPCON acts and interferes with bone morphogenenic (BMP) signaling, is not known, but BMP signaling pathway is controlled by receptors types 1 and 2 in a cascade regulated at multiple levels where FOPCON may modulate.

The function of propranolol is not explained solely by these factors. Propranolol is one of the drugs indicated for cardiovascular and other clinical applications such as migraine, anxiety and glaucoma (22), and is a nonselective beta-blocker antagonist, which blocks the action of both adrenaline and noradrenalin adrenergic receptors such as β1 and β2. Also, propranolol can act as a partial agonist of one or more serotonin receptors (22,23).

Reports on the therapeutic combination of AA and PP concomitantly are rare, which includes atrial fibrillation treatment (24) and clinical pharmacokinetics study of drug interactions (25). Nevertheless, AA has recently been shown to regulate expression of a battery of genes (26), but PP has not yet been investigated in this regard. In vivo AA modulates the expression of inflammatory genes (27) and in vitro, modulates target genes related to FOP pathology (28).

The autonomous nervous system has been lately, strongly linked to inflammatory processes, specially the sympathetic system as a pro-inflammatory branch (29). FOP and its symptoms involve the autonomic nervous system and neurohumoral mechanisms. A neurogenic pain in FOP patients has been recently described and to be of a more intense degree than reported for the general population (30). The pain and emotional symptoms of FOP must be targeted as neuro-inflammatory symptoms for clinical treatment. Our three FOP patient cases improved considerably, being free from body pain after FOPCON.

4. Conclusion

In conclusion, the composition of AA and PP can be effectively useful, if administered previously and continually, for prophylaxis of flare-ups due to accidental falls. FOPCON may benefit patients in future surgical procedures by preventing them from having the severe sequels characteristic of heterotopic bone formation. All three patients reported, to date, no longer had flare-ups nor heterotopic ossification and showed normal scar formation without sequelae. The monitoring of younger patients like P3, who still do not have all the heterotopic bone formation in advanced stages that immobilize most patients in bed, will allow us to see, in the coming years, the effect of FOPCON blocking the deplorable evolution of FOP.
